

### **QUESTION:**

Write a solution to find the ids of products that are both low fat and recyclable.

Return the result table in **any order**.

Table: **Products**

+-----+-----+	
Column Name	Type
+-----+-----+	
product_id	int
low_fats	enum
recyclable	enum
+-----+-----+	

product\_id is the primary key (column with unique values) for this table.

low\_fats is an ENUM (category) of type ('Y', 'N') where 'Y' means this product is low fat and 'N' means it is not.

recyclable is an ENUM (category) of types ('Y', 'N') where 'Y' means this product is recyclable and 'N' means it is not.

### **Intuition:**

We need to find where in the table the products are both low fat and recyclable.

### **Approach:**

Use ( ' ' ) quotation Marks in the WHERE statement to specify which Value in the column we want to get. Use the GROUP BY statement to combine the product ids Into single row results.

### **ANSWER:**

```
SELECT product_id
FROM Products
WHERE low_fats = 'Y' AND recyclable = 'Y'
GROUP BY product_id
```

Accepted

### **Products =**

product_id	low_fats	recyclable
0	Y	N
1	Y	Y
2	N	Y
3	Y	Y
4	N	N

### **Output**

product_id
1
3

### **Expected**

product_id
1
3

The screenshot shows a coding platform interface. On the left, the 'Description' tab is active, displaying the 'Products' table schema and a problem statement. The table has columns: product\_id (int, primary key), low\_fats (enum with values 'Y', 'N'), and recyclable (enum with values 'Y', 'N'). The problem asks to find the IDs of products that are both low fat and recyclable, returning the result in any order. The result format is shown as a table with product\_id.

In the center, the 'Code' editor shows a MySQL query:

```
1 # Write your MySQL query statement below
2 SELECT product_id
3 FROM Products
4 WHERE low_fats = 'Y' AND recyclable = 'Y'
5 GROUP BY product_id
```

On the right, the 'Test Result' section shows the 'Output' and 'Expected' results, both displaying a table with product\_id values 1 and 3.

**QUESTION:**

Find the names of the customer that are **not referred by** the customer with id = 2.

Return the result table in **any order**.

The result format is in the following example.

Table: **Customer**

+-----+-----+	
Column Name   Type	
+-----+-----+	
id	int
name	varchar
referee_id	int
+-----+-----+	

In SQL, id is the primary key column for this table.

Each row of this table indicates the id of a customer, their name, and the id of the customer who referred them.

**Intuition:**

We want to find all customers that do not have a referee id with the value 2 although there are customers that have referee id values of null, so we have to change those to 0

**Approach:**

Use COALESCE to handle Null values and replace them with 0's. Use (<>) less than or greater than to get return all without 2. SELECT name because that is the only column we need.

### **ANSWER:**

```
SELECT name
FROM Customer
WHERE COALESCE(referee_id,0) <> 2
```

Accepted

### **Customer =**

```
| id | name | referee_id | | -- | ---- | ----- | | 1 | Will | null | | 2 | Jane | null | | 3 | Alex | 2 | | 4 |
Bill | null | | 5 | Zack | 1 | | 6 | Mark | 2 |
```

### **Output**

```
| name | | ---- | | Will | | Jane | | Bill | | Zack |
```

### **Expected**

```
| name | | ---- | | Will | | Jane | | Bill | | Zack |
```

The screenshot shows a coding platform interface with the following components:

- Problem List:** A navigation bar at the top with icons for Problem List, Run, Submit, and other functions.
- Description:** A section on the left containing the problem description and a table schema for the 'Customer' table.
- Code Editor:** A central area with a code editor showing the SQL query: 

```
1 # Write your MySQL query statement below
2 SELECT name
3 FROM Customer
4 WHERE COALESCE(referee_id,0) <> 2
```
- Testcase:** A section on the right showing the test result, which matches the expected output.

**Table: Customer**

Column Name	Type
id	int
name	varchar
referee_id	int

In SQL, id is the primary key column for this table. Each row of this table indicates the id of a customer, their name, and the id of the customer who referred them.

Find the names of the customer that are **not referred by** the customer with `id = 2`.

Return the result table in **any order**.

The result format is in the following example.

**Example 1:**

2.1K 205

**Output**

```
| name |
| ---- |
| Will |
| Jane |
| Bill |
| Zack |
```

**Expected**

```
| name |
| ---- |
| Will |
| Jane |
| Bill |
| Zack |
```

**QUESTION:**

Write a solution to report the product\_name, year, and price for each sale\_id in the Sales table.

Return the resulting table in **any order**.

Table: **Sales**

+-----+-----+

| Column Name | Type |

+-----+-----+

| sale\_id | int |

| product\_id | int |

| year | int |

| quantity | int |

| price | int |

+-----+-----+

(sale\_id, year) is the primary key (combination of columns with unique values) of this table.

product\_id is a foreign key (reference column) to Product table.

Each row of this table shows a sale on the product product\_id in a certain year.

**Note:** that the price is per unit.

Table: **Product**

+-----+-----+

| Column Name | Type |

+-----+-----+

| product\_id | int |

| product\_name | varchar |

+-----+-----+

product\_id is the primary key (column with unique values) of this table.

Each row of this table indicates the product name of each product.

**Intuition:**

We need to use LEFT JOIN to combine the two tables, then we can query results from there. Being that both Product\_id columns are keys we will use the USING clause in our LEFT JOIN statement.

**Approach:**

Use p. As an indicator for The product table and s. As an indicator for the product table. Remember to clarify s and p when calling the tables.

**ANSWER:**

```
SELECT p.product_name, s.year, s.price
FROM Sales s
LEFT JOIN Product p USING (product_id)
```

Accepted

**Sales =**

sale_id   product_id   year   quantity   price	-----	-----	----	-----	----	1	100
2008   10   5000	2   100	2009   12   5000	7   200	2011   15   9000			

## Product =

| product\_id | product\_name | | ----- | ----- | | 100 | Nokia | | 200 | Apple | | 300 | Samsung |

## Output

| product\_name | year | price | | ----- | ---- | ---- | | Nokia | 2008 | 5000 | | Nokia | 2009 | 5000 | | Apple | 2011 | 9000 |

## Expected

| product\_name | year | price | | ----- | ---- | ---- | | Nokia | 2009 | 5000 | | Nokia | 2008 | 5000 | | Apple | 2011 | 9000 |

DescriptionEditorialNote X SolutionsSubmissions

Table: Product

Column Name	Type
product_id	int
product_name	varchar

product\_id is the primary key (column with unique values) of this table.  
Each row of this table indicates the product name of each product.

Write a solution to report the product\_name, year, and price for each sale\_id in the Sales table.

Return the resulting table in **any order**.

The result format is in the following example.

**Example 1:**

876 95

Code

MySQLAuto

```
1 # Write your MySQL query statement below
2 SELECT p.product_name, s.year, s.price
3 FROM Sales s
4 LEFT JOIN Product p USING (product_id)
```

SavedLn 2, Col 1

TestcaseTest Result

Output

product_name	year	price
Nokia	2008	5000
Nokia	2009	5000
Apple	2011	9000

Expected

product_name	year	price
Nokia	2009	5000
Nokia	2008	5000
Apple	2011	9000

**QUESTION:**

Write a solution to find the IDs of the users who visited without making any transactions and the number of times they made these types of visits.

Return the result table sorted in **any order**.

Table: **Visits**

+-----+-----+	
Column Name	Type
+-----+-----+	
visit_id	int
customer_id	int
+-----+-----+	

visit\_id is the column with unique values for this table.

This table contains information about the customers who visited the mall.

Table: **Transactions**

+-----+-----+	
Column Name	Type
+-----+-----+	
transaction_id	int
visit_id	int
amount	int
+-----+-----+	

transaction\_id is column with unique values for this table.

This table contains information about the transactions made during the visit\_id.

**Intuition:**

We want to find the ids that are associated with the null values and group them together by the amount of times they visited.

### **Approach:**

Once again we are going to use LEFT JOIN, although this time we are going to add the WHERE statement and use the IS clause to find the NULL value, then GROUP BY to finish our query.

### **ANSWER:**

```
SELECT customer_id, Count(v.visit_id) AS count_no_trans
FROM Visits v
LEFT JOIN Transactions t ON t.visit_id = v.visit_id
WHERE transaction_id IS NULL
GROUP BY customer_id
```

Accepted

### **Visits =**

visit_id	customer_id
1	23
2	9
4	30
5	54
6	96
7	54

### **Transactions =**

transaction_id	visit_id	amount
2	5	310
3	5	300
9	5	200
12	1	910
13	2	970

### **Output**

customer_id	count_no_trans
30	1
96	1
54	2

### **Expected**

customer_id	count_no_trans
30	1
96	1
54	2

**Description** | **Editorial** | **Note** | **Solutions** | **Submissions**

transaction\_id is column with unique values for this table. This table contains information about the transactions made during the visit\_id.

Write a solution to find the IDs of the users who visited without making any transactions and the number of times they made these types of visits.

Return the result table sorted in **any order**.

The result format is in the following example.

**Example 1:**

**Input:**

visit_id	customer_id
1	23
2	9
4	30

**Output**

customer_id	count_no_trans
30	1
96	1
54	2

**Expected**

customer_id	count_no_trans
30	1
96	1
54	2

**Code**

```
1 # Write your MySQL query statement below
2 SELECT customer_id, Count(v.visit_id) AS count_no_trans
3 FROM Visits v
4 LEFT JOIN Transactions t ON t.visit_id = v.visit_id
5 WHERE transaction_id IS NULL
6 GROUP BY customer_id
```

**Testcase** | **Test Result**

**QUESTION:**

Write a solution to find the number of times each student attended each exam.

Return the result table **ordered by** student\_id and subject\_name.

Table: **Students**

+-----+-----+	
Column Name	Type
+-----+-----+	
student_id	int
student_name	varchar
+-----+-----+	

student\_id is the primary key (column with unique values) for this table.

Each row of this table contains the ID and the name of one student in the school.

Table: **Subjects**

+-----+-----+	
Column Name	Type
+-----+-----+	
subject_name	varchar
+-----+-----+	

subject\_name is the primary key (column with unique values) for this table.

Each row of this table contains the name of one subject in the school.

Table: **Examinations**

+-----+-----+	
Column Name	Type
+-----+-----+	
student_id	int
subject_name	varchar
+-----+-----+	

There is no primary key (column with unique values) for this table. It may contain duplicates.

Each student from the Students table takes every course from the Subjects table.

Each row of this table indicates that a student with ID student\_id attended the exam of subject\_name.

***Intuition:***

We need to join all three tables then count the number of of times each student has taken the test indicated by the subject Id.

***Approach:***

Not all columns match and the Examinations table doesn't have a primary key so we are going to combine CROSS JOIN AND LEFT JOIN so we can specify which columns match which from the Examinations table.

***ANSWER:***

```
SELECT st.student_id, st.student_name, su.subject_name, COUNT(e.subject_name) AS
attended_exams
FROM Students st
CROSS JOIN Subjects su
LEFT JOIN Examinations e ON su.subject_name=e.subject_name AND
e.student_id=st.student_id
GROUP BY st.student_id, st.student_name, su.subject_name
ORDER BY st.student_id, su.subject_name
```

Accepted

***Students =***

```
| student_id | student_name | | ----- | ----- | | 1 | Alice | | 2 | Bob | | 13 | John | | 6 | Alex |
```

## Subjects =

| subject\_name | | ----- | | Math | | Physics | | Programming |

## Examinations =

| student\_id | subject\_name | | ----- | ----- | | 1 | Math | | 1 | Physics | | 1 |  
Programming | | 2 | Programming | | 1 | Physics | | 1 | Math | | 13 | Math | | 13 | Programming | |  
13 | Physics | | 2 | Math | | 1 | Math |

## Output

| student\_id | student\_name | subject\_name | attended\_exams | | ----- | ----- | -----  
----- | ----- | | 1 | Alice | Math | 3 | | 1 | Alice | Physics | 2 | | 1 | Alice | Programming | 1 | |  
2 | Bob | Math | 1 | | 2 | Bob | Physics | 0 | | 2 | Bob | Programming | 1 | | 6 | Alex | Math | 0 | | 6 |  
Alex | Physics | 0 | | 6 | Alex | Programming | 0 | | 13 | John | Math | 1 | | 13 | John | Physics | 1 | |  
13 | John | Programming | 1 |

## Expected

| student\_id | student\_name | subject\_name | attended\_exams | | ----- | ----- | -----  
----- | ----- | | 1 | Alice | Math | 3 | | 1 | Alice | Physics | 2 | | 1 | Alice | Programming | 1 | |  
2 | Bob | Math | 1 | | 2 | Bob | Physics | 0 | | 2 | Bob | Programming | 1 | | 6 | Alex | Math | 0 | | 6 |  
Alex | Physics | 0 | | 6 | Alex | Programming | 0 | | 13 | John | Math | 1 | | 13 | John | Physics | 1 | |  
13 | John | Programming | 1 |

The screenshot shows a coding platform interface with three main sections:

- Description:** Contains a table schema for 'Students' and 'Subjects', a text explanation of the problem, and the required output format.
- Code:** A MySQL query editor showing a SQL query to select student information and the count of exams attended.
- Testcase / Test Result:** Displays the output of the query as a table.

**Table Schema:**

Column Name	Type
student_id	int
subject_name	varchar

**Problem Description:**

There is no primary key (column with unique values) for this table. It may contain duplicates. Each student from the Students table takes every course from the Subjects table. Each row of this table indicates that a student with ID student\_id attended the exam of subject\_name.

**Write a solution to find the number of times each student attended each exam.**

**Return the result table ordered by student\_id and subject\_name.**

**The result format is in the following example.**

**Example 1:**

**Input:**

Students table:

**Expected Output:**

student_id	student_name	subject_name	attended_exams
1	Alice	Math	3
1	Alice	Physics	2
1	Alice	Programming	1
2	Bob	Math	1
2	Bob	Physics	0
2	Bob	Programming	1

**QUESTION:**

Write a solution to find the **confirmation rate** of each user.

Return the result table in **any order**

Table: **Signups**

+-----+	
Column Name	Type
+-----+	
user_id	int
time_stamp	datetime
+-----+	

Each row contains information about the signup time for the user with ID user\_id.

Table: **Confirmations**

+-----+	
Column Name	Type
+-----+	
user_id	int
time_stamp	datetime
action	ENUM
+-----+	

(user\_id, time\_stamp) is the primary key (combination of columns with unique values) for this table.

user\_id is a foreign key (reference column) to the Signups table.

action is an ENUM (category) of the type ('confirmed', 'timeout')

The **confirmation rate** of a user is the number of 'confirmed' messages divided by the total number of requested confirmation messages. The confirmation rate of a user that did not request any confirmation messages is 0. Round the confirmation rate to **two decimal** places.

**Intuition:**

We need to find the confirmation rate which will be the average of confirmed values in the action column from the confirmations table.

**Approach:**

Using AVG(if(...)) we can find the average if the value if it returns a 1 signifying the value is confirmed. 0 returned is not confirmed. Then ROUND those values by 2 decimal places.

**ANSWER:**

```
SELECT s.user_id, ROUND(
    AVG(if(c.action="confirmed",1,0)),2)
    AS confirmation_rate
FROM Signups s
LEFT JOIN Confirmations c ON s.user_id = c.user_id
GROUP BY 1
Accepted
```

**Signups =**

```
| user_id | time_stamp | | ----- | ----- | | 3 | 2020-03-21 10:16:13 | | 7 | 2020-01-04
13:57:59 | | 2 | 2020-07-29 23:09:44 | | 6 | 2020-12-09 10:39:37 |
```

## Confirmations =

```
| user_id | time_stamp | action | | ----- | ----- | ----- | | 3 | 2021-01-06 03:30:46  
| timeout | | 3 | 2021-07-14 14:00:00 | timeout | | 7 | 2021-06-12 11:57:29 | confirmed | | 7 |  
2021-06-13 12:58:28 | confirmed | | 7 | 2021-06-14 13:59:27 | confirmed | | 2 | 2021-01-22  
00:00:00 | confirmed |
```

## Output

```
| user_id | confirmation_rate | | ----- | ----- | | 3 | 0 | | 7 | 1 | | 2 | 0.5 | | 6 | 0 |
```

## Expected

```
| user_id | confirmation_rate | | ----- | ----- | | 6 | 0 | | 3 | 0 | | 7 | 1 | | 2 | 0.5 |
```

The screenshot shows a SQL editor interface with the following components:

- Table: Signups**

Column Name	Type
user_id	int
time_stamp	datetime

user\_id is the column of unique values for this table.  
Each row contains information about the signup time for the user with ID user\_id.
- Table: Confirmations**

Column Name	Type
user_id	int
time_stamp	datetime
action	ENUM

(user\_id, time\_stamp) is the primary key (combination of columns)
- Code Editor**

```
1 # Write your MySQL query statement below
2 SELECT s.user_id, ROUND(
3     AVG(if(c.action="confirmed",1,0)),2)
4     AS confirmation_rate
5 FROM Signups s
6 LEFT JOIN Confirmations c ON s.user_id = c.user_id
7 GROUP BY 1
```

2	0.5
6	0
- Expected**

user_id	confirmation_rate
6	0
3	0
7	1
2	0.5

### **QUESTION:**

Write a solution to report the movies with an odd-numbered ID and a description that is not "boring".

Table: ***Cinema***

+-----+-----+	
Column Name	Type
+-----+-----+	
id	int
movie	varchar
description	varchar
rating	float
+-----+-----+	

id is the primary key (column with unique values) for this table.

Each row contains information about the name of a movie, its genre, and its rating.

rating is a 2 decimal places float in the range [0, 10]

Return the result table ordered by rating **in descending order**.

### **Intuition:**

The main part we need to focus on in this query is returning the odd number IDs. If you divide even numbers by 2 you will always have a remainder of 0, odd numbers will have a non zero remainder.

### **Approach:**

In the WHERE clause, in addition to the description (!=) not equal to 'boring',  $(id \% 2) <> 0$  IDs divided by 2 with a remainder less than or greater than 0

## ANSWER:

```
SELECT *  
FROM Cinema  
WHERE (id % 2) <> 0 AND description != 'boring'  
ORDER BY rating DESC
```

Accepted

**cinema =**

```
| id | movie | description | rating | | -- | ----- | ----- | ----- | | 1 | War | great 3D | 8.9 | | 2 |  
Science | fiction | 8.5 | | 3 | irish | boring | 6.2 | | 4 | Ice song | Fantasy | 8.6 | | 5 | House card |  
Interesting | 9.1 |
```

## Output

```
| id | movie | description | rating | | -- | ----- | ----- | ----- | | 5 | House card | Interesting  
| 9.1 | | 1 | War | great 3D | 8.9 |
```

## Expected

```
| id | movie | description | rating | | -- | ----- | ----- | ----- | | 5 | House card | Interesting  
| 9.1 | | 1 | War | great 3D | 8.9 |
```

The screenshot shows a SQL editor interface with the following components:

- Table: Cinema**

Column Name	Type
id	int
movie	varchar
description	varchar
rating	float

id is the primary key (column with unique values) for this table. Each row contains information about the name of a movie, its genre, and its rating.  
rating is a 2 decimal places float in the range [0, 10]
- Code Editor**

```
1 # Write your MySQL query statement below  
2 SELECT *  
3 FROM Cinema  
4 WHERE (id % 2) <> 0 AND description != 'boring'  
5 ORDER BY rating DESC
```
- Testcase / Test Result**

Output

id	movie	description	rating
5	House card	Interesting	9.1
1	War	great 3D	8.9

Expected

id	movie	description	rating
5	House card	Interesting	9.1
1	War	great 3D	8.9

**QUESTION:**

Write an SQL query that reports the **average** experience years of all the employees for each project, **rounded to 2 digits**.

Table: ***Project***

+-----+-----+	
Column Name	Type
+-----+-----+	
project_id	int
employee_id	int
+-----+-----+	

(project\_id, employee\_id) is the primary key of this table.

employee\_id is a foreign key to Employee table.

Each row of this table indicates that the employee with employee\_id is working on the project with project\_id.

Table: ***Employee***

+-----+-----+	
Column Name	Type
+-----+-----+	
employee_id	int
name	varchar
experience_years	int
+-----+-----+	

employee\_id is the primary key of this table. It's guaranteed that experience\_years is not NULL.

Each row of this table contains information about one employee.

Return the result table in **any order**.

**Intuition:**

We will use LEFT JOIN in this query because we want to show the project\_id from one table and the aggregated experience\_years from the other table

**Approach:**

Simple ROUND and AVG functions that we've used before, make sure to group the results by the project\_id numbers.

**ANSWER:**

```
SELECT p.project_id, ROUND(
    AVG(e.experience_years),2) AS average_years
FROM Project p
LEFT JOIN Employee e ON p.employee_id=e.employee_id
GROUP BY p.project_id
```

Accepted

**Project =**

```
| project_id | employee_id | | ----- | ----- | | 1 | 1 | | 1 | 2 | | 1 | 3 | | 2 | 1 | | 2 | 4 |
```

**Employee =**

```
| employee_id | name | experience_years | | ----- | ----- | ----- | | 1 | Khaled | 3 | |
2 | Ali | 2 | | 3 | John | 1 | | 4 | Doe | 2 |
```

### Output

project_id	average_years	-----	-----	1	2	2	2.5
------------	---------------	-------	-------	---	---	---	-----

**Expected**

project_id	average_years	-----	-----	1	2	2	2.5
------------	---------------	-------	-------	---	---	---	-----

[illegible]

**QUESTION:**

Write a solution to find the average selling price for each product. average\_price should be **rounded to 2 decimal places**.

Table: **Prices**

+-----+	
Column Name	Type
+-----+	
product_id	int
start_date	date
end_date	date
price	int
+-----+	

(product\_id, start\_date, end\_date) is the primary key (combination of columns with unique values) for this table.

Each row of this table indicates the price of the product\_id in the period from start\_date to end\_date.

For each product\_id there will be no two overlapping periods. That means there will be no two intersecting periods for the same product\_id.

Table: **UnitsSold**

+-----+	
Column Name	Type
+-----+	
product_id	int
purchase_date	date
units	int
+-----+	

Each row of this table indicates the date, units, and product\_id of each product sold.

Return the result table in **any order**.

**Intuition:**

We need to add in a formula to calculate the average price of each product. The prices change based on when they were purchased and some purchases have multiple of the same products.

**Approach:**

The formula we are going to use is the total amount of units at their current price divided by the total amount of units. We also need to specify that the purchase dates are in between the start\_date and end\_date of our Prices table. This will let the system know the current price at time of purchase.

**ANSWER:**

```
SELECT p.product_id, COALESCE(ROUND(
    SUM(u.units * p.price)/SUM(u.units),2),0)
    AS average_price
FROM Prices p
LEFT JOIN UnitsSold u on p.product_id = u.product_id AND u.purchase_date BETWEEN
p.start_date AND p.end_date
GROUP BY p.product_id
Accepted
```

**Prices =**

[illegible]

## UnitsSold =

```
| product_id | purchase_date | units | | ----- | ----- | ---- | | 1 | 2019-02-25 | 100 | | 1 |  
2019-03-01 | 15 | | 2 | 2019-02-10 | 200 | | 2 | 2019-03-22 | 30 |
```

## Output

```
| product_id | average_price | | ----- | ----- | | 1 | 6.96 | | 2 | 16.96 |
```

## Expected

```
| product_id | average_price | | ----- | ----- | | 1 | 6.96 | | 2 | 16.96 |
```

The screenshot shows a SQL editor interface with a table schema, a query, and its results.

**Table: Prices**

Column Name	Type
product_id	int
start_date	date
end_date	date
price	int

(product\_id, start\_date, end\_date) is the primary key (combination of columns with unique values) for this table.  
Each row of this table indicates the price of the product\_id in the period from start\_date to end\_date.  
For each product\_id there will be no two overlapping periods. That means there will be no two intersecting periods for the same product\_id.

**Table: UnitsSold**

Column Name	Type
product_id	int

**Code**

```
1 # Write your MySQL query statement below  
2 SELECT p.product_id, COALESCE(ROUND(  
3     SUM(u.units * p.price) / SUM(u.units), 2), 0)  
4     AS average_price  
5 FROM Prices p  
6 LEFT JOIN UnitsSold u ON p.product_id = u.product_id AND u.purchase_date BETWEEN  
7     p.start_date AND p.end_date  
8 GROUP BY p.product_id
```

**Testcase** **Test Result**

**Output**

product_id	average_price
1	6.96
2	16.96

**Expected**

product_id	average_price
1	6.96
2	16.96

### **QUESTION:**

Write a solution to find the percentage of the users registered in each contest rounded to **two decimals**.

Table: ***Users***

+-----+-----+	
Column Name	Type
+-----+-----+	
user_id	int
user_name	varchar
+-----+-----+	

user\_id is the primary key (column with unique values) for this table.

Each row of this table contains the name and the id of a user.

Table: ***Register***

+-----+-----+	
Column Name	Type
+-----+-----+	
contest_id	int
user_id	int
+-----+-----+	

(contest\_id, user\_id) is the primary key (combination of columns with unique values) for this table.

Each row of this table contains the id of a user and the contest they registered into.

Return the result table ordered by percentage in **descending order**. In case of a tie, order it by contest\_id in **ascending order**.

### **Intuition:**

We don't need to show columns from both tables, we are just comparing the ids to their aggregated percentage results. We can use a sub query.

### **Approach:**

We need to divide the COUNT OF unique Id's in the Register table, multiplied by 100. By the COUNT of all Id's in the Users table and call that the percentage column.

### **ANSWER:**

```
SELECT contest_id,  
ROUND(COUNT(DISTINCT user_id) * 100 / (SELECT Count(user_id) FROM Users), 2) AS  
percentage  
FROM Register  
GROUP BY contest_id  
ORDER BY percentage DESC, contest_id
```

Accepted

### **Users =**

user_id	user_name
6	Alice
2	Bob
7	Alex

### **Register =**

contest_id	user_id
215	6
209	2
208	2
210	6
208	6
209	7

### **Output**

contest_id	percentage
208	100
209	100
210	100
215	66.67
207	33.33

### **Expected**

contest_id	percentage
208	100
209	100
210	100
215	66.67
207	33.33

SQL 50

Write a solution to find the percentage of the users registered in each contest rounded to **two decimals**.

Return the result table ordered by **percentage** in **descending order**. In case of a tie, order it by **contest\_id** in **ascending order**.

The result format is in the following example.

**Example 1:**

**Input:**

Users table:

user_id	user_name
6	Alice
2	Bob
7	Alex

Register table:

contest_id	user_id
215	6

```
1 # Write your MySQL query statement below  
2 SELECT contest_id,  
3 ROUND(COUNT(DISTINCT user_id) * 100 / (SELECT Count(user_id) FROM Users), 2) AS  
4 percentage  
5 FROM Register  
6 GROUP BY contest_id  
7 ORDER BY percentage DESC, contest_id
```

Testcase Test Result

Output

contest_id	percentage
208	100
209	100
210	100
215	66.67
207	33.33

Expected
